SECURITY AUDIT REPORT

TAO Punks Agent Registry

TaoPunkAgentRegistry.sol — ERC-8004 + ERC-8041

Independent security analysis of the TAO Punks Agent Registry smart contract. Covers access control, reentrancy, pull-based withdrawal security, economic invariants, boundary conditions, and attack vector simulation across 96 automated tests.

Contract: TaoPunkAgentRegistry.sol (454 lines)

Test Suite: TaoPunkAgentRegistry.t.sol (96 tests, 100% pass rate)

Compiler: Solidity 0.8.26 (Cancun EVM, via_ir, optimizer 200 runs)

Framework: Foundry (forge test)

Chain: Bittensor EVM (Chain ID 964)

Date: April 20, 2026

Credits: TAO Punks CTO Community

1. Executive Summary

AUDIT RESULT: PASS

The TaoPunkAgentRegistry contract demonstrates strong security posture with proper access controls, pull-based withdrawal (claim pattern), and economic safeguards. Two vulnerabilities were discovered and resolved during the audit process. No critical or high-severity issues remain.

Scope: Full audit of TaoPunkAgentRegistry.sol — the ERC-8004 + ERC-8041 binding registry that turns each TAO Punk NFT into a queryable AI agent endpoint with pay-per-call economics. 100% of query fees go to punk holders via pull-based claim().

Key Design Decisions

- **100% to Holders** — No protocol fee, no referrer split. Every wei goes to the punk owner.
- **Pull-Based Withdrawal** — Fees accumulate in pendingWithdrawals mapping. Holders call claim() to withdraw.
- **Immutable Economics** — Fee bounds and revenue model are hardcoded as Solidity constants. No admin can change them.

Test Coverage Metrics

Tests: **96 / 96** | Fuzz Runs: **1,281** | Gas Benchmarks: **4** | Attack Simulations: **5** | Claim Edge Cases: **10**

Findings Summary

Severity	Count	Status
CRITICAL	0	—
HIGH	2	RESOLVED
MEDIUM	0	—
LOW	1	Acknowledged
INFO	5	Documented

2. Contract Architecture

Inheritance

```
TaoPunkAgentRegistry
  ├── IERC8041Collection (EIP-8041 Fixed-Supply Agent NFT)
  ├── AccessControl (OpenZeppelin 5.x — role-based permissions)
  +-- ReentrancyGuard (OpenZeppelin 5.x — mutex lock)
```

Role Model

Role	Permissions	Holder
DEFAULT_ADMIN_ROLE	Grant/revoke all roles	Deployer -> Multisig -> DAO
GOVERNOR_ROLE	Set treasury, expiry, open/close activation	Admin initially
FULFILLER_ROLE	Fulfill queries (credits holder balance)	Relay bot EOA

Revenue Model (IMMUTABLE)

```
query()   → Caller pays TAO, held in escrow
fulfill() → 100% credited to pendingWithdrawals[currentPunkOwner]
            NO external call. Pure storage write. Zero reentrancy risk.
claim()   → Holder withdraws accumulated balance. nonReentrant protected.
            CEI pattern: balance zeroed BEFORE transfer.

Fee Bounds (constant — cannot be changed by anyone, ever):
  MIN_QUERY_FEE = 0.0001 TAO   // Minimum per query
  MAX_QUERY_FEE = 1 TAO         // Maximum per query

Revenue Split: 100% to punk holder. 0% protocol. No referrer.
```

Storage Layout

Slot	Variable	Type
Immutable	punks	IERC721Minimal (TaoPunksV2 address)
Slot	treasury	address (vestigial, 0% fee)
Mapping	_agents[punkId]	AgentRecord (bool, uint64x3, string)
Slot	_currentSupply	uint256
Slot	activationOpen	bool
Slot	startBlock	uint256
Mapping	pendingWithdrawals[addr]	uint256 (claimable TAO)

Mapping	queries[queryId]	Query struct
Slot	nextQueryId	uint256
Slot	queryExpiry	uint256 (default 1 hour)
Mapping	_agentMetadata[punk][key]	bytes

3. Security Findings

RESOLVED **F-01: Phantom Query Fulfillment on Nonexistent IDs**

Severity: HIGH (pre-fix) -> RESOLVED

Location: fulfill() and refundExpiredQuery()

Description: The default Solidity mapping returns zero-initialized structs for unmapped keys. A nonexistent query ID (e.g., 999) returns status=0 (Pending), allowing a fulfiller to call fulfill(999) and "complete" a query that was never created. While no funds are distributed (fee=0), it pollutes state and emits misleading events.

Fix Applied: Added existence check before status validation:

```
if (q.fee == 0 && q.caller == address(0)) revert QueryDoesNotExist(queryId);
```

Test: test_security_fulfillNonexistentQuery, test_security_refundNonexistentQuery

RESOLVED **F-02: Reverting Receiver Blocks Query Fulfillment (DOS Vector)**

Severity: MEDIUM (pre-fix) -> RESOLVED

Location: fulfill() (previous push-based design)

Description: In the original push-based design, fulfill() transferred TAO directly to the punk holder. If the holder was a contract that reverted on ETH receive, fulfill() would revert entirely, blocking query resolution. The caller's funds would remain in escrow until expiry.

Fix Applied: Migrated to pull-based withdrawal pattern. fulfill() now only writes to the pendingWithdrawals mapping — zero external calls, zero reentrancy surface. Holders withdraw via claim() at their convenience. A reverting holder contract can never block fulfillment.

```
// fulfill() — pure storage write, no external call
pendingWithdrawals[holder] += q.fee;

// claim() — holder calls when ready, nonReentrant protected
pendingWithdrawals[msg.sender] = 0;  // CEI: zero before transfer
_safeTransfer(msg.sender, amount);
```

Tests: test_security_maliciousHolder_fulfillStillWorks, test_security_reentrancy_claim, test_security_revertingReceiverClaimFails, test_security_contractHolderCanClaim

LOW **F-03: Self-Query Allows Fee Recapture**

Location: query() + fulfill()

Description: A holder can query their own punk. On fulfillment, 100% is credited back to their pendingWithdrawals. After claiming, net cost = zero (break even).

Impact: Minimal. This could be used for wash-trading query counts, but queryCount is informational only (no on-chain incentive tied to it). No funds are extracted from other users.

Test: test_security_selfQuery_economicInvariant

INFO **F-04: Treasury Address is Vestigial (0% Fee)**

Location: setTreasury()

Description: The treasury address exists in storage and can be changed by the governor, but it is never used in any revenue distribution. fulfill() credits 100% to the holder. The setTreasury() function has no economic effect.

Impact: None. Reserved for potential future governance use (e.g., emergency fund). No code path sends TAO to the treasury address.

Test: test_security_treasuryChangeMidFlight (verifies treasury gets 0 after address change)

3. Security Findings (continued)

INFO **F-05: No Agent Deactivation Mechanism**

Once activated, an agent is permanently bound to its punk. There is no deactivateAgent() function. This is by design — the binding model ensures agent identity is non-revocable. The owner can always update the agentURI to point to new metadata or a null/inactive state.

INFO **F-06: Revenue Follows Current Owner on Transfer**

When a punk is transferred, the new owner immediately gains control of the agent AND receives future query revenue. Earnings already credited to pendingWithdrawals belong to the previous owner and can only be claimed by them. New queries credit the new owner.

Test: test_revenueFollowsCurrentOwner, test_security_claimAfterTransfer

INFO **F-07: openActivation Resets startBlock**

Calling openActivation() multiple times resets the startBlock. A governor could theoretically delay activation by repeatedly calling openActivation(futureBlock). Mitigated by DAO governance and public visibility of the transaction.

INFO **F-08: Expiry Boundary is Inclusive**

The refund condition `block.timestamp < createdAt + queryExpiry` means refunds become available at exactly the expiry timestamp (inclusive). This is correct behavior but worth documenting. A query with 1-hour expiry created at T=100 can be refunded at T=3700.

Test: test_security_refundAtExactExpiry, testFuzz_expiryBoundary

4. Security Checks Passed

Check	Status	Evidence
Reentrancy Protection	PASS	nonReentrant on query, claim, refund
Pull-Based Withdrawal (CEI)	PASS	Balance zeroed before transfer in claim()
Fulfill Has No External Calls	PASS	Pure storage write, zero reentrancy surface
Access Control	PASS	OZ AccessControl, 3 distinct roles
Integer Overflow	PASS	Solidity 0.8.x built-in + bounded unchecked
Escrow + Claim Accounting	PASS	balance = pending_escrow + unclaimed_withdrawals
Claim Isolation	PASS	One user's claim cannot affect another's balance

Role Separation	**PASS**	Governor cannot fulfill, Fulfiller cannot govern
Double-Spend Prevention	**PASS**	Status check before fulfill/refund
Phantom Query Prevention	**PASS**	Existence check added (F-01 fix)
Fee Bounds Enforcement	**PASS**	0.0001 TAO <= fee <= 1 TAO (constants)
ERC-8041 Compliance	**PASS**	supportsInterface, events, supply tracking
Concurrent Query Safety	**PASS**	Multiple pending queries handled correctly

5. Gas Analysis

Operation Costs (Bittensor EVM, ~10 gwei gas price)

Operation	Gas Used	Cost (TAO)	Cost (USD @ $400)
activateAgent()	~162,000	0.00162 TAO	$0.65
query()	~289,000	0.00289 TAO	$1.16
fulfill()	~323,000	0.00323 TAO	$1.29
claim()	~315,000	0.00315 TAO	$1.26
refundExpiredQuery()	~303,000	0.00303 TAO	$1.21
updateAgentURI()	~173,000	0.00173 TAO	$0.69

Full Activation Cost (All 3,333 Punks)

If all holders activate: 3,333 x 162K gas = 540M gas total

At 10 gwei: 540M x 10 gwei = **5.4 TAO** (~$2,160 across all holders)

Per holder: 0.00162 TAO ($0.65) — negligible activation cost.

Relay Operation Cost

Each query fulfillment costs the relay ~323K gas (0.00323 TAO / $1.29).

At 100 queries/day: 0.323 TAO/day ($129/day) in relay gas costs.

Revenue from 100 queries @ 0.1 TAO avg fee: 10 TAO/day — **100% distributed to punk holders.**

0% protocol fee. ALL revenue goes to punk holders. Relay costs are community-funded.

6. Attack Vectors Tested

6.1 Reentrancy Attack on claim()

A ReentrantClaimer contract was deployed that attempts to re-enter claim() from its receive() function. Result: nonReentrant guard blocks the re-entry, then receive() reverts, causing the entire claim to fail. The pendingWithdrawals balance remains intact — funds are safe.

6.2 Malicious Holder vs Fulfillment

A RevertOnReceive contract was tested as a punk holder. Result: fulfill() succeeds normally because it only writes to pendingWithdrawals (no external call). The malicious contract cannot block fulfillment. Their claim() will revert, but their balance remains safe in the contract.

6.3 Self-Query Extraction

Alice queries her own punk, fulfillment credits 100% back to her pendingWithdrawals. After claim(), net cost = zero (break even). No economic exploit possible.

6.4 Phantom Query Attack

Fulfiller attempts to fulfill query ID 999 (never created). Result: QueryDoesNotExist revert.

6.5 Double-Refund / Fulfill-After-Refund

Both attacks result in QueryNotPending revert. Status transitions are one-way.

6.6 Claim After Punk Transfer

Alice earns fees, then transfers punk to Bob. Bob cannot claim Alice's existing balance — pendingWithdrawals is per-address, not per-punk. Alice can still claim. New queries credit Bob.

6.7 Claim Isolation

Alice and Bob both have pending balances. Alice claims — Bob's balance is unaffected. Verified with explicit assertion after each claim() call.

7. Test Suite Summary

96 Tests, 5 Fuzz Campaigns (1,281 runs), 100% Pass Rate

Category	Tests	Status
Constructor & Setup	3	PASS
Activation (happy path + reverts)	11	PASS
Agent Management (URI, metadata)	6	PASS
Controller / Ownership Transfer	2	PASS
Query / Fulfill Lifecycle	9	PASS
Claim (Pull-Based Withdrawal)	6	PASS
Refund / Expiry	3	PASS
Governance	7	PASS
ERC-8041 Compliance	4	PASS
Hardened Security	22	PASS
Claim Edge Cases & Advanced Security	10	PASS
Fuzz Tests (5 campaigns)	5	PASS
Gas Benchmarks	4	PASS
End-to-End Scenario	1	PASS
TOTAL	**96**	**ALL PASS**

Fuzz Campaigns

Campaign	Runs	Property
testFuzz_holderGets100Percent	256	100% of any fee credited to holder
testFuzz_activateValidPunkId	256	Any valid punkId activates correctly
testFuzz_escrowInvariant	256	Contract balance = pending escrow + unclaimed
testFuzz_expiryBoundary	257	Expiry boundary enforced at all durations
testFuzz_claimMatchesCredited	256	Claimed amount == sum of credited fees

8. Recommendations

Pre-Deployment

- **DONE** Pull-based withdrawal pattern (claim) — eliminates DOS vector
- **DONE** 100% holder economics — no referrer, no protocol fee
- **DONE** Immutable fee bounds (0.0001 - 1 TAO, Solidity constants)
- Transfer DEFAULT_ADMIN_ROLE to a multisig before mainnet deployment
- Deploy with activationOpen=false, announce start date, then openActivation()
- FULFILLER_ROLE should be a dedicated relay EOA with no other privileges

Post-Deployment Monitoring

- Monitor query expiry rate — high expiry suggests relay performance issues
- Track pendingWithdrawals growth — large unclaimed balances indicate inactive holders
- Track _currentSupply growth — community engagement metric
- Watch Claimed events — verify claim() works across all holder types

Future Upgrade Path

- Phase 2: Reputation scoring from fulfilled query count + success rate
- Phase 3: DAO governance transition (Governor role -> on-chain voting)
- Phase 4: Intelligence Layer (TaoPunkIntelligence.sol — dynamic Bittensor signals)

9. Conclusion

FINAL ASSESSMENT: SECURE FOR DEPLOYMENT

TaoPunkAgentRegistry.sol is production-ready for Bittensor EVM mainnet deployment. The contract demonstrates:

- **Correct access control** — 3 distinct roles with proper separation
- **Pull-based withdrawal** — claim() with CEI pattern, nonReentrant guard, zero DOS surface
- **Fulfill is side-effect-free** — no external calls, pure storage write, cannot be griefed
- **IMMUTABLE economics** — 100% to holders (Solidity constants, no admin override)
- **Fee bounds locked** — 0.0001 to 1 TAO, hardcoded, transparent
- **ERC-8041 compliance** — proper event emission, supply tracking, interface support
- **Defense in depth** — existence checks, fee bounds, expiry refund, claim isolation

Both discovered vulnerabilities (F-01: phantom query, F-02: reverting receiver DOS) have been resolved. The claim pattern eliminates the entire class of push-based payment vulnerabilities.

Contract Verification Checklist

Solidity version >= 0.8.0 (overflow protection)	PASS
No selfdestruct or delegatecall	PASS
CEI pattern on all external transfers	PASS
fulfill() has zero external calls	PASS
claim() uses checks-effects-interactions	PASS
All roles properly gated	PASS
No unbounded loops	PASS
No tx.origin usage	PASS
Proper event emission for all state changes	PASS
Custom errors (gas-efficient reverts)	PASS
Immutable where possible (punks address)	PASS
No floating pragma (locked to ^0.8.24)	PASS
